

CONGRUENCES MODULO POWERS OF 2 FOR THE NUMBER OF UNIQUE PATH PARTITIONS

C. KRATTENTHALER

ABSTRACT. We compute the congruence class modulo 16 of the number of unique path partitions of n (as defined by Olsson), thus generalising previous results by Bessenrodt, Olsson and Sellers [*Ann. Combin.* **13** (2013), 591–602].

1. INTRODUCTION

Unique path partitions were introduced by Olsson in [3]. Their study is motivated from the Murnaghan–Nakayama rule for the calculation of the value of characters of the symmetric group. They were completely characterised by Bessenrodt, Olsson and Sellers in [1]. They used this characterisation to derive a formula for the generating function for the number $u(n)$ of all unique path partitions of n . This formula reads (cf. [1, Remark 3.6])

$$\begin{aligned} \sum_{n \geq 1} u(n)q^n &= 2 \sum_{i \geq 1} q^{2^i-1} (1 + q^{2^{i-1}}) \prod_{j=0}^{i-2} \frac{1}{1 - q^{2^j}} \\ &= 2 \left(q(1 + q) + \sum_{i \geq 2} \frac{q^{-1} + 1}{1 - q^2} \cdot \frac{q^{2^i} (1 + q^{2^{i-1}})}{\prod_{j=1}^{i-2} (1 - q^{2^j})} \right). \end{aligned} \quad (1.1)$$

The final part in [1] concerns congruences modulo 8 for $u(n)$. The corresponding main result [1, Theorem 4.6] provides a complete description of the behaviour of $u(n)$ modulo 8 (in terms of the related sequence of numbers $w(n)$; see the next section for the definition of $w(n)$). The arguments to arrive at this result are mainly of a recursive nature.

The purpose of this note is to show that a more convenient and more powerful method to derive congruences (modulo powers of 2) is by an analysis of the generating function (1.1). Not only are we able to recover the result from [1], but in addition we succeed in determining the congruence class of $u(n)$ modulo 16, see (2.1) and Theorem 7, thus solving the problem left open in the last paragraph of [1]. We point out that the approach presented here is very much inspired by calculations in [2, Appendix], where expressions similar to the one on the right-hand side of (1.1) appear, with the role of the prime number 2 replaced by 3, though.

Key words and phrases. Unique path partitions, congruences, q -series.

[†]Research partially supported by the Austrian Science Foundation FWF, grants Z130-N13 and S50-N15, the latter in the framework of the Special Research Program “Algorithmic and Enumerative Combinatorics”.

In the next section, we show how to obtain congruences modulo 8 for $w(n)$, which, by (2.1), translate into congruences modulo 16 for the unique path partition numbers $u(n)$.

3. CONGRUENCES MODULO POWERS OF 2

In what follows, we write

$$f(q) = g(q) \text{ modulo } 2^\gamma$$

to mean that the coefficients of q^i in $f(q)$ and $g(q)$ agree modulo 2^γ for all i . We apply geometric series expansion in (2.3), and at the same time we neglect terms which are divisible by 8. For example, we expand

$$\frac{1}{1 - \frac{2q}{1+q^2}} = 1 + \frac{2q}{1+q^2} + \frac{4q^2}{(1+q^2)^2} \text{ modulo } 8.$$

In this manner, we obtain the congruence

$$\begin{aligned} \sum_{n \geq 2} w(n)q^n &= \sum_{i \geq 1} q^{2^{2i-1}} \left(1 + \frac{2q^{2^{2i-2}}}{1 - q^{2^{2i-2}}} + 2 \sum_{j=0}^{i-2} \frac{q^{2^{2j}}}{1 + q^{2^{2j+1}}} \right. \\ &\quad \left. + 4 \frac{q^{2^{2i-2}}}{1 - q^{2^{2i-2}}} \sum_{j=0}^{i-2} \frac{q^{2^{2j}}}{1 + q^{2^{2j+1}}} + 4 \sum_{0 \leq s \leq t \leq i-2} \frac{q^{2^{2s}+2^{2t}}}{(1 + q^{2^{2s+1}})(1 + q^{2^{2t+1}})} \right) \\ &\quad + \sum_{i \geq 1} q^{2^{2i}} \left(1 + 2 \sum_{j=0}^{i-1} \frac{q^{2^{2j}}}{1 + q^{2^{2j+1}}} + 4 \sum_{0 \leq s \leq t \leq i-1} \frac{q^{2^{2s}+2^{2t}}}{(1 + q^{2^{2s+1}})(1 + q^{2^{2t+1}})} \right) \\ &\quad \text{modulo } 8. \end{aligned}$$

After rearrangement, this becomes

$$\begin{aligned} \sum_{n \geq 2} w(n)q^n &= \sum_{i \geq 1} q^{2^i} + \frac{2q^3}{1-q} + 2 \sum_{j \geq 1} \frac{1}{1 - q^{2^{2j}}} \left(q^{2^{2j}+2^{2j+1}} + q^{2^{2j-2}}(1 - q^{2^{2j-1}}) \sum_{\ell \geq 2j} q^{2^\ell} \right) \\ &\quad + 4 \sum_{1 \leq s < t} \frac{q^{2^{2s-2}+2^{2t-2}}}{(1 - q^{2^{2s-1}})(1 - q^{2^{2t-1}})} \left(q^{2^{2t-1}}(1 + q^{2^{2t-2}}) + \sum_{\ell \geq 2t} q^{2^\ell} \right) \\ &\quad + 4 \sum_{s \geq 1} \frac{q^{2^{2s-1}}}{(1 - q^{2^{2s}})} \sum_{\ell \geq 2s} q^{2^\ell} \quad \text{modulo } 8. \end{aligned} \tag{3.1}$$

We must now analyse the individual sums in (3.1).

Lemma 1. *Let $n \geq 2$, and write $n = \sum_{i=a}^e n_i \cdot 2^i$, with $0 \leq n_i \leq 1$ for all i and $n_a \neq 0 \neq n_e$. Then the coefficient of q^n in*

$$\sum_{j \geq 1} \frac{q^{2^{2j}+2^{2j+1}}}{1 - q^{2^{2j}}} \tag{3.2}$$

is equal to $\lfloor a/2 \rfloor$ if n is not a power of 2, and it is equal to $\max\{\lfloor a/2 \rfloor - 1, 0\}$ otherwise.

Proof. By geometric series expansion, we see that the coefficient of q^n in (3.2) is equal to the number of possibilities to write $n = (k+3)2^{2j}$ for some $j \geq 1$ and $k \geq 0$. For fixed j , we can find a suitable k if and only if $n \geq 3 \cdot 2^{2j}$. If n is not a power of 2, this is equivalent to the condition that $2j \leq a$. The claim follows immediately. \square

Lemma 2. Let $n \geq 2$, and write $n = \sum_{i=a}^e n_i \cdot 2^i$ as in Lemma 1. Then the coefficient of q^n in

$$\sum_{j \geq 1} \frac{q^{2^{2j-2}}}{1 - q^{2^{2j}}} \sum_{\ell \geq 2j} q^{2^\ell} \quad (3.3)$$

is equal to $e - 2j + 1$ if $a = 2j - 2$, $n_{a+1} = n_{2j-1} = 0$, and n is not a power of 2, and it is equal to 0 otherwise.

Proof. By geometric series expansion, we see that the coefficient of q^n in (3.3) is equal to the number of possibilities to write $n = 2^{2j-2} + k \cdot 2^{2j} + 2^\ell$ for some $j \geq 1$, $\ell \geq 2j$, and $k \geq 0$. The claim follows immediately. \square

Lemma 3. Let $n \geq 2$, and write $n = \sum_{i=a}^e n_i \cdot 2^i$ as in Lemma 1. Then the coefficient of q^n in

$$\sum_{j \geq 1} \frac{q^{2^{2j-2} + 2^{2j-1}}}{1 - q^{2^{2j}}} \sum_{\ell \geq 2j} q^{2^\ell} \quad (3.4)$$

is equal to $e - 2j + 1$ if $a = 2j - 2$, $n_{a+1} = n_{2j-1} = 1$, and it is equal to 0 otherwise.

Proof. By geometric series expansion, we see that the coefficient of q^n in (3.4) is equal to the number of possibilities to write $n = 2^{2j-2} + 2^{2j-1} + k \cdot 2^{2j} + 2^\ell$ for some $j \geq 1$, $\ell \geq 2j$, and $k \geq 0$. The claim follows immediately. \square

Lemma 4. Let $n \geq 2$, and write $n = \sum_{i=a}^e n_i \cdot 2^i$ as in Lemma 1. Then the coefficient of q^n in

$$\sum_{s \geq 1} \frac{q^{2^{2s-1}}}{1 - q^{2^{2s}}} \sum_{\ell \geq 2s} q^{2^\ell} \quad (3.5)$$

is equal to $e - 2s + 1$ if $a = 2s - 1$ and n is not a power of 2, and it is equal to 0 otherwise.

Proof. By geometric series expansion, we see that the coefficient of q^n in (3.5) is equal to the number of possibilities to write $n = 2^{2s-1} + k \cdot 2^{2s} + 2^\ell$ for some $s \geq 1$, $\ell \geq 2s$, and $k \geq 0$. The claim follows immediately. \square

Lemma 5. Let $n \geq 2$, and write $n = \sum_{i=a}^e n_i \cdot 2^i$ as in Lemma 1. Then the coefficient of q^n in

$$\sum_{1 \leq s < t} \frac{q^{2^{2s-2} + 2^{2t-2}}}{(1 - q^{2^{2s-1}})(1 - q^{2^{2t-1}})} \sum_{\ell \geq 2t-1} q^{2^\ell} \quad (3.6)$$

is congruent to

$$e \sum_{i=a+2}^{e - \chi(e \text{ even})} n_i - a \cdot n_{a+2} + \left\lfloor \frac{1}{2}(e - a - 1) \right\rfloor \pmod{2}, \quad (3.7)$$

where $\chi(\mathcal{S}) = 1$ if \mathcal{S} is true and $\chi(\mathcal{S}) = 0$ otherwise.

Proof. By geometric series expansion, we see that the coefficient of q^n in (3.6) is equal to the number of possibilities to write

$$n = (2k_1 + 1)2^{2s-2} + (2k_2 + 1)2^{2t-2} + 2^{2t-1+k_3} \quad (3.8)$$

for some s and t with $1 \leq s < t$ and $k_1, k_2, k_3 \geq 0$. Clearly, we need a to be even in order that the number of these possibilities be non-zero. Given that $a = 2s - 2$, we just

have to count the number of possible triples (t, k_2, k_3) in (3.8), since the appropriate k_1 can certainly be found. If we fix t and k_3 , the number of possible k_2 's is

$$\left\lfloor \frac{1}{2} \cdot \frac{n - 2^{2t-1+k_3}}{2^{2t-2}} + \frac{1}{2} \right\rfloor = \left\lfloor \frac{n}{2^{2t-1}} + \frac{1}{2} \right\rfloor - 2^{k_3}.$$

This needs to be summed over all t and k_3 with $\frac{1}{2}(a+2) = s < t \leq \frac{1}{2}(e+1)$ and $0 \leq k_3 \leq e - 2t + 1$. We obtain

$$\begin{aligned} & \sum_{t=s+1}^{\lfloor \frac{1}{2}(e+1) \rfloor} \sum_{k_3=0}^{e-2t+1} \left(\left\lfloor \frac{n}{2^{2t-1}} + \frac{1}{2} \right\rfloor - 2^{k_3} \right) \\ & \equiv \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} \sum_{k_3=0}^{e-2t+1} \left[n_a \cdot 2^{a-2t+1} + \cdots + (n_{2t-2} + 1) \cdot 2^{-1} \right. \\ & \quad \left. + n_{2t-1} + n_{2t} \cdot 2 + \cdots + n_e \cdot 2^{e-2t+1} \right] - \left\lfloor \frac{1}{2}(e-a-1) \right\rfloor \\ & \equiv \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} (e-2t+2)(n_{2t-2} + n_{2t-1}) + \left\lfloor \frac{1}{2}(e-a-1) \right\rfloor \\ & \equiv e \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} n_{2t-1} + e \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e-1) \rfloor} n_{2t} + (e-a)n_{a+2} + \left\lfloor \frac{1}{2}(e-a-1) \right\rfloor \pmod{2}. \end{aligned}$$

□

Lemma 6. Let $n \geq 2$, and write $n = \sum_{i=a}^e n_i \cdot 2^i$ as in Lemma 1. Then the coefficient of q^n in

$$\sum_{1 \leq s < t} \frac{q^{2s-2+2^{2t}}}{(1-q^{2^{2s-1}})(1-q^{2^{2t-1}})} \quad (3.9)$$

is congruent to

$$\sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} n_{2t-1} + \left\lfloor \frac{1}{2}(e-a-1) \right\rfloor. \pmod{2}. \quad (3.10)$$

Proof. By geometric series expansion, we see that the coefficient of q^n in (3.9) is equal to the number of possibilities to write

$$n = (2k_1 + 1)2^{2s-2} + (k_2 + 2)2^{2t-1} \quad (3.11)$$

for some s and t with $1 \leq s < t$ and $k_1, k_2 \geq 0$. Clearly again, we need a to be even in order that the number of these possibilities be non-zero. Given that $a = 2s - 2$, we just have to count the number of possible pairs (t, k_2) in (3.11), since the appropriate k_1 can certainly be found. If we fix t , the number of possible k_2 's is

$$\left\lfloor \frac{n - 2^{2t}}{2^{2t-1}} + 1 \right\rfloor = \left\lfloor \frac{n}{2^{2t-1}} \right\rfloor - 1.$$

This needs to be summed over all t with $\frac{1}{2}(a+2) = s < t \leq \frac{1}{2}(e+1)$. We obtain

$$\begin{aligned} \sum_{t=s+1}^{\lfloor \frac{1}{2}(e+1) \rfloor} \left(\left\lfloor \frac{n}{2^{2t-1}} \right\rfloor - 1 \right) &\equiv \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} \left[n_a \cdot 2^{a-2t+1} + \cdots + n_{2t-2} \cdot 2^{-1} \right. \\ &\quad \left. + (n_{2t-1} - 1) + n_{2t} \cdot 2 + \cdots + n_e \cdot 2^{e-2t+1} \right] \\ &\equiv \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} n_{2t-1} - \left\lfloor \frac{1}{2}(e-a-1) \right\rfloor \pmod{2}. \quad \square \end{aligned}$$

We are finally in the position to state and prove our main result. It expresses the congruence class of $w(n)$ modulo 8 — and thus, by (2.1), the congruence class of the unique path partition number $u(n)$ modulo 16 — in terms of the binary digits of n . We point out that the assertion (3.12) already appeared in [1, Prop. 4.5].

Theorem 7. *Let $n \geq 2$, and write $n = \sum_{i=a}^e n_i \cdot 2^i$ as in Lemma 1. Then, if $a = e$ (i.e., if n is a power of 2), the number $w(n)$ is congruent to*

$$2 \lfloor a/2 \rfloor + 1 \pmod{8}, \quad (3.12)$$

while it is congruent to

$$\begin{aligned} &2 + 2 \lfloor a/2 \rfloor + 2\chi(a \text{ even})(1 - 2n_{a+1})(e - a - 1) + 4\chi(a \text{ odd})(e - a) \\ &+ 4\chi(a \text{ even}) \left(e \sum_{i=a+2}^{e-\chi(e \text{ even})} n_i + a \cdot n_{a+2} + \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} n_{2t-1} \right) \pmod{8} \quad (3.13) \end{aligned}$$

otherwise.

Proof. Let first $n = 2^a$. We must then read the coefficient of q^n on the right-hand side of (3.1) and reduce the result modulo 8. Non-zero contributions come from the very first sum, from the series $2q^3/(1-q^2)$, and from the series which is discussed in Lemma 1. Altogether, we obtain

$$1 + 2\chi(a \geq 2) + 2 \max\{\lfloor a/2 \rfloor - 1, 0\},$$

which can be simplified to (3.12).

Now let n be different from a power of 2. The non-zero contributions when reading the coefficient of q^n on the right-hand side of (3.1) come again from the series $2q^3/(1-q^2)$, and from the series discussed in Lemmas 1–6. These contributions add up to

$$\begin{aligned} &2\chi(n \geq 3) + 2 \lfloor a/2 \rfloor + 2\chi(a \text{ even}, n_{a+1} = 0)(e - a - 1) \\ &+ 2\chi(a \text{ even}, n_{a+1} = 1)(e - a - 1) + 4\chi(a \text{ odd})(e - a) \\ &+ 4\chi(a \text{ even}) \left(e \sum_{i=a+2}^{e-\chi(e \text{ even})} n_i - a \cdot n_{a+2} + \left\lfloor \frac{1}{2}(e-a-1) \right\rfloor + \sum_{t=\frac{1}{2}(a+4)}^{\lfloor \frac{1}{2}(e+1) \rfloor} n_{2t-1} + \left\lfloor \frac{1}{2}(e-a-1) \right\rfloor \right). \end{aligned}$$

This expression can be simplified to result in (3.13). \square

It is clear that, in the same way, one could also derive a result for $w(n)$ modulo 16, 32, ..., albeit at the cost of considerably more work.
